245

Report on the Fauna of Ireland : Div. Invertebrata. Drawn up, at the request of the British Association, by WILLIAM THOMPSON, Esq., President of the Natural History and Philosophical Society of Belfast.

Introduction.

In the former portion of my Report on the Fauna of Ireland, laid before the meeting of the British Association at Glasgow in 1840, the Vertebrata only were included*. In the continuation now presented, are all the native species of Invertebrata—Mollusca, Crustacea, Cirrhipeda, Annelida, Foraminifera, Entozoa, Echinodermata, Acalepha, Zoophyta, Amorphozoa-excepting Insecta and Infusoria, using the former term in its widest sense.

For the whole of the information in some departments I am indebted to others : of a portion undertaken by myself, I have only yet obtained a superficial knowledge. A want of unity will be observable throughout in the treatment of the various subjects, the most obvious point of which to some naturalists will be in the nomenclature :--- the first names bestowed on the species, which according to the just rule of priority (see British Association Rules of Nomenclature) should be those used, could only be partially ascertained within the allotted time. This Report does not embrace so comprehensive a view as I originally contemplated with respect to widely-extended comparisons, and the causes which seem to operate on the distribution of the various classes, &c. of Invertebrata, but as now given, it may afford data to others better qualified to do justice to that subject. It will in its present state only have a value in recording the species indigenous to Ireland, and offering a comparison between them and those of Great Britain, but this is not unimportant with regard even to the general geographical distribution of species. The European Fauna, it need scarcely be observed, could not be perfected without that of Ireland being known, which latter is again especially interesting, in consequence of our island being within its latitude the extreme western limit to which all the species included in it range that are peculiar to the eastern, or in other words, are not found in the western hemisphere.

The Fauna of Ireland, compared with that of Great Britain, exhibits the falling off of species westerly compared with that island, which again on its part (though not treated of here) presents a similar falling off westerly compared with the opposite shore of the continent. An example may be necessary in explanation, and the most striking will be selected, though the subjectmatter belong to the former part of this Report. Thus, of the class Reptilia there are in BELGIUMT. GREAT BRITAIN. IRELAND. Order Sauria. Lacerta 3 species... 2 species (same as Belg.)... 1 species (same as Brit.). Anguis..... 1 ,, ... 1 ,, ... 0 ,, ,,

* The species of Vertebrata since added to our catalogue are--Turdus Whitei, Eyton, Ann. Nat. Hist. vol. xi. p. 78. Pycnonotus chrysorrhæus, Swains. See present volume. Cuculus glandarius, Lin., Ann. Nat. Hist. vol. xii. p. 149, and present volume. Glareola pratincola, Lin. (sp.) See present volume. Naucrates ductor, Cuv. and Val. See present volume. The Lepus Hibernicus and L. variabilis are now proved to be of the same species (see present volume): respecting the animal provisionally called Mus Hibernicus no further information has been obtained.

It appears therefore	that the deficiency of]	Ireland compared with Great

Britain in the *Reptilia*, is much upon the same scale as that of the latter island compared with Belgium.

There is not any island of similar extent to Ireland, and in like manner situated with respect to other lands, with which to compare it. The islands of New Zealand within temperate latitudes in the southern hemisphere may however be mentioned as possessing of indigenous *Mammalia*[†], Bats alone, of which one species has been described [‡]; and no Ophidian reptiles. "Throughout the present Report (to quote from the former portion) it must be borne in mind, that all species found from the Channel Islands in the south, to the Shetland Islands in the north, are included in the fauna of Great Britain, and that within the degrees of latitude over which it extends, Ireland occupies but one-third. Ireland is comprised within four degrees, while the Shetland Islands range nearly six degrees further to the north, and more than two degrees to the south the Channel Islands are situated. The Fauna of Great Britain also extends over ten degrees of longitude, while that of Ireland is limited to half the number."

The physical geography and climate need not be dwelt on here, as in the case of the Mammalia Terrestria, Aves, and Reptilia, as the land Mollusca and Annelides only will be directly affected by such influences. The freshwater Mollusca, Crustacea, Annelida and Amorphozoa will be affected, but less directly, by the physical geography, taken in connection with the mineralogical structure of the country; as will the marine species in some degree, by the nature and quantity of the residuum brought by rivers to the sea. The physical geography of the bottom of the sea will have a powerful effect on the marine Invertebrata of all kinds, even greater than that of the dry land on its animals. According to the configuration and depth, to the mineralogical character of the rocks, the vegetation, &c., shall we find particular families, genera, and species. Even where the configuration and depth are similar, the oozy, sandy, gravelly, or rocky bottom, will have each its peculiar animals. It has not been thought desirable, as in the Report on the Vertebrata, to treat distinctly of every species, as to its being common or rare, &c.; but in-

* Rana Scotica and Triton Bibronii, of which so little is known, either as to distribution or otherwise, are not enumerated.

† In Mammalia, Belgium has two genera—*Crocidura* and *Cricetus*—not found in Great Britain, in which are four—*Rhinolophus*, *Talpa*, *Myoxus*, *Arvicola*—unknown to Ireland. De Selys-Longchamps believes Belgium to be the most northern limit of the genus *Crocidura*, and states that it is not met with in Holland or Denmark.

[‡] The species is *Vespertilio tuberculatus*, Forster. J. E. Gray in Deiffenbach's New Zealand, vol. ii. p. 181. According to the Report of the United States' Exploring Expedition, published in the Edinburgh Philosophical Journal for January 1844;— "none of the Pacific Islands, including New Zealand, contain any native Mammalia

247

stead, to leave this to be indicated by the tabular mark of distribution, although it may often prove unsatisfactory. Thus, species which have been found but once on each side of the island are marked as conspicuously under north, east, west and south, as those which are abundant round the coast. But naturalists will not be deceived by this; none will imagine that because *Eulima subulata* exhibits the same number of asterisks as *Rissoa ulvæ*, that the species are equally plentiful; but all will know that the former, though widely distributed, is found in extremely limited numbers, and the latter in abundance where they respectively occur. Nor, was it deemed necessary in so brief a summary, to give the authorities for the occurrence of the various species; but reference is made throughout to the works in which all the details published respecting them will be found.

MOLLUSCA.

Catalogues of the testaceous Mollusca of Ireland, elaborated during the residence of their respective authors in this country, were drawn up about the

same time by Capt. Brown and Dr. Turton*, in which they were aided by the collections of Mr. O'Kelly of Dublin, Dr. Thomas Taylor (species contributed by Miss Hutchins of Bantry), Mr. Samuel Wright of Cork, Mrs. Clewlow, Dr. McGee, Dr. McDonnell, and Mr. Templeton of Belfast+. Mr. Templeton, before and after the period of their researches, was silently noting down for future publication all that he could learn upon the subject, but, stationary at his country residence, he was less favourably circumstanced than either of those gentlemen, by whom various parts of the country and coast were visited. Their inquiries, directed to a single branch of natural history, were naturally more productive in that one department than his, whose survey embraced the whole Flora and Fauna of Ireland, for the illustration of which he was diligently collecting materials. To Bryce's 'Tables of Simple Minerals, Rocks and Shells,' found in three of the northern counties, Mr. Hyndman contributed a few hitherto unnoticed species. The native Mollusca, more especially of Youghal and Dublin, have been effectively collected and studied by Mr. Robert Ball, aided by his sister Miss M. Ball; as have those of Limerick and Miltown Malbay, on the western coast, by Mr. Wm. Henry Harvey; those of Cork by Mr. John Humphreys, and those of the northern shores by Mr. Geo. C. Hyndman. A few species of the highest interest from the northern province have been obtained by Dr. J. L. Drummond, as have some from the southern by Dr. Geo. J. Allman. The extensive and beautiful collections of Mr. T. W. Warren and Dr. Farran of Dublin, more particularly of species from the neighbouring coast—the richest in Ireland have rendered most important aid towards an elucidation of the subject. The Ordnance collection has contributed in so far as the comparatively poor coast investigated could afford. Mrs. Hancock has rendered essential service by assiduously collecting the species of the western shores, at Ballysodare in the county of Sligo, and Bundoran in the county of Donegal, and transmitting them to Belfast, where they came under the inspection of Mr. Hyndman and myself.

* Capt. Brown's memoir was dated from Naas Barracks, Ireland, Aug. 20, 1815, and read before the Wernerian Society of Edinburgh on the 16th of December in that year (see Wern. Mem. vol. ii.). Dr. Turton's appeared in the 'Dublin Examiner, or Monthly Miscellany of Literature, Science and Art,' in July 1816. In the subsequent works of these authors additional Irish species were described : all in the following catalogue that are noticed by them only (i. e. unknown to my correspondents and myself) are marked as on their authority.

⁺ At a subsequent period, the collection of James Rose Clealand, Esq. of Bangor in the county of Down, contributed some interesting species to Sowerby, &c.

REPORT-1843.

Those who have given attention to the Testaceous Mollusca generally have hitherto been alluded to. The native land and freshwater species exclusively have been well studied by the Rev. Benj. J. Clarke, Mr. Edward Waller, and the Rev. Thomas Hincks (late of Cork). Several other naturalists and collections might be named, but those enumerated are among the principal.

The species added to our Fauna from the preceding sources and from personal investigation, have been noticed in 'Additions to the Fauna of Ireland,' published in the 'Annals of Natural History' (vol. v. vii. xiii.); in vol. v. a description of *Limneus involutus*, and a contribution on the *Mollusca Nudibranchia* and *Moll. Tunicata* will be found: in vol. vi. is a catalogue of the land and freshwater Mollusca.

Although I had some time since with considerable labour brought together in manuscript all that has been published on the Irish Mollusca, and looked over all the collections possible, I have critically studied a small portion only of the subject. Without the aid therefore of my scientific friends, Mr. Alder of Newcastle-upon-Tyne and Professor Edward Forbes, the Mollusca as a whole could not have been undertaken. In the *Gasteropoda Nudibranchia* and the marine Testaceous tribes their assistance has been most valuable. Some naturalists will consider the number of British species alluded to in the remarks on the different Orders much under what it should be. This arises from my adoption of the British list, as expurgated by the two distinguished malacologists whose aid has been alluded to. A number of species which have from time to time been introduced without sufficient evidence are omitted; a number more are reduced to mere varieties; and species figured or described in such a manner as not to be understood by the best informed on the subject, are unnoticed.

In the Classes and Orders, Rang's 'Manuel des Mollusques' is chiefly followed.

It has been considered sufficient throughout this Report simply to indicate the north, east, west and south. The Mollusca of the following localities have been more or less investigated :—North, Coasts of Londonderry and Antrim.—East, Counties of Antrim, Down, Louth, Dublin, Wicklow.—West, Bundoran, co. Donegal; Bally-sodare, co. Sligo; Birterbury and Roundstone bays (Dr. Farran); Clifden, Killery and Clew bays,&c., (R. Ball, E. Forbes, G. C. Hyndman, W. T.) in the counties of Mayo and Galway; Miltown Malbay, co. Clare.—South, Bantry Bay, Youghal, Cork harbour.
† (I.) throughout the Report denotes species known as Irish, and not as British.

The larger native Cephalopoda were noticed in the old county histories, and a few additional species have been briefly indicated by myself in the 'Proceedings of the Zoological Society' (1834), p. 31, and in the 'Annals of Nat. Hist.' vol. v. p. 10. Mr. R. Ball, in bringing before the Royal Irish Academy a notice of a new species of Loligo (L. Eblanæ) on Nov. 30, 1839, announced the other indigenous species of that genus*, and on the 10th of January, 1842, described before the same Society two new species of Rossia, and noticed all the Irish species of Cephalopoda of which he was cognisant. These are published in the Proceedings of the Royal Irish Academy of that date. An Eledone in my possession, from Belfast bay, though closely allied to E. octopodia, seems to be distinct. Octopus vulgaris is given on the authority of Templeton only, who remarks that it is "not uncommon," an expression which, taken in connection with the omission of Eled. octopodia from his catalogue, leads me to believe that this latter was probably the species meant. If the Octopus vulgaris be included, the Irish list contains all the British species excepting Eledone Aldrovandi, described by Mr. Macgillivray within the present year in his 'Mollusca of Aberdeenshire.' Five of the Irish Cephalopoda—Sepia rupellaria, Loligo subulata, L. Eblanæ, Rossia Oweni, R. Jacobi-are not known as British species.

Distribution.

South

North

East.

Class PTEROPODA.

Hyalæa trispinosa, Cuv. (Anim. King. by Griff. vol. xii. Mollusca, pl. 3. f. 7.) (I.)
Peracle Flemingi, Forbes †; Fusus retroversus, Flem.

No species of this class can be noted with certainty as taken on the coast of Great Britain, it being doubtful whether the *Peracle Flemingi* belong to the *Pteropoda*. This species is only known as Irish from some specimens being found by Mr. Hyndman in shell-sand collected by Mrs. Hancock at Bundoran, on the coast of Donegal, in the summer of 1840. Of *Hyalæa trispinosa* a single example with the contained animal was found by Mr. R. Ball on the beach near Youghal, county of Cork, some years ago, and at the same time with three species of the pedunculated *Cirrhipeda*, (*A. lævis*, *A. sulcata*, *A. fascicularis*) a *Spirula australis*, and an *Ianthina communis*. The *Anatifæ* were attached to the mast of a vessel, and in their "tangled mass" the *Hyalæa* and *Spirula* occurred.

Class GASTEROPODA.

. Order Nucleobranchiata.

This order was first introduced to the British Fauna at the present meeting by Professor E. Forbes, who a few years since obtained examples of it in the Frith of Forth and British Channel in a species which he has named *Sagitta Britannica*. About the same time, Dr. G. J. Allman obtained similar Mollusca (of which he made drawings) on the coast of Cork, but whether they be of the same species is uncertain.

Twenty species of *Nudibranchia* were recorded as Irish in $1840 \parallel$, a number equal to that known to be British in 1828, when Dr. Fleming's 'British Animals'

* "(sp.)" throughout the Report denotes the specific name, and it only, to be that of the author quoted.

 \uparrow Mr. Alder, after an examination of the specimens so designated, considers that they are not the true *E. rufibranchialis*: I have therefore proposed the above name, as from the sketches and minute description of the species in Dr. J. L. Drummond's journal, it has become properly understood.

 \ddagger The species of *Eolis* not named was dredged at Donaghadee in May 1843, by Dr. Drummond, but unfortunately a description was not made out at the time of its capture. The specimen on being submitted to Mr. Alder was stated to be certainly distinct from any of the preceding and to come nearest in form to his *E. concinna* and *E. vittata*, though probably distinct from either of them.

§ Alderia is a new genus of Dr. Allman's, as Proctonotus is of Messrs. Alder and

appeared. Since the latter period the British catalogue of species belonging to this beautiful order of Mollusca has been greatly augmented by the labours of Dr. Johnston*, Mr. Edward Forbes†, Mr. Alder‡, and Mr. Hancock, and above all by the two latter gentlemen, who, studying the subject conjointly, have by the very complete and philosophical manner in which their investigations were conducted, thrown the greatest light upon the order *Nudibranchia*. The number of British species now known is sixty-five §, of which twentythree have been met with in Ireland; to these latter are to be added eleven

species unknown as British, making the number of Irish altogether thirty-four -of these eleven, two constitute new genera, and the remaining nine are, with the exception of the Doris muricata of the 'Zoologia Danica,' believed to be new species and are indicated in the preceding catalogue by the initial "(I.)" All of the British genera but two—*Eubranchus* and *Calliopæa* $\|$ have been procured on the Irish coast; the former is known only from its occurrence in one instance to Mr. Forbes in the Isle of Man; the latter was as a British genus announced for the first time at the present meeting: upon the Irish coast only the new genera Proctonotus and Alderia have been obtained. The genus *Proctonotus*, together with two new species of *Eolis* and seven species known as British, but not hitherto as Irish ¶, were added to our catalogue by Mr. Alder last autumn during little more than three days' examination of the Dublin coast: within a similar time about equally good results have been obtained by Mr. Hyndman and myself in another locality, Strangford lough; instances which show how much may be done in the Nudibranchia within a very limited period. Mr. Alder (who in conjunction with Mr. Hancock is engaged in a monograph of the whole of the British species belonging to this order) having expressed a desire to examine my specimens noticed in the fifth and seventh volumes of the 'Annals of Natural History,' they were at once placed in his hands. This has unexpectedly proved serviceable to myself on the present occasion, as I have had the benefit of his revision of what had been written on the Irish species. Mr. Alder's information on the subject so far surpasses my own, that his opinion has been implicitly followed throughout the preceding catalogue with respect to what are good species, what only varieties, &c. Distribution.

The *Pulmonifera* of Ireland being treated of very fully in the sixth volume of the Annals of Natural History, it need only be stated here, that the British catalogue contains nineteen species[†], which are not in the Irish, and the latter three, which are not in the former. These are *Geomalacus maculosus*, *Limax gagates*, and *Limneus involutus*; the *Limax arboreus*, though unpublished as a British species, is not included, as I have found it to be as common in Ayrshire and the Isle of Wight, as in Ireland. The generic forms which have not a place in the Irish catalogue are *Azeca* and *Segmentina*.

Class GASTEROPODA.

Order Pulmonifera Operculata.

Cyclostoma elegans, Mull. (sp.) * *

This is the only British species of the Order. A single specimen of the *Cyclostoma productum* is stated by Dr. Turton to have been found by himself in the west of Ireland. Manual Brit. Land, &c. Shells, p. 94.

> Class GASTEROPODA. Order *Pectinibranchiata*. Fam. *Turbinidæ*.

* I have been enabled to include the *Amph. glutinosa* since this Report was sent to press, through the kind attention of Mr. Wm. Andrews of Dublin, who favoured me with specimens collected by him last summer in the canal near that city.

† In this number, two species are included which have not been found northward of the Channel Islands; the others are partially distributed in England, and two or three only reach so far north as Scotland.

[‡] Mr. Alder thinks E. polita of Macgillivray's Aberdeenshire Mollusca may be this species.

Of about 160 species of British *Pectinibranchia*, 35 are unknown as Irish; they are the rarest species, and the greater number of them have been met with only in a single locality—not one is of common occurrence. About 12 species obtained in Ireland have not a place in the British catalogue. The British genera unknown as Irish, are *Turbo**, *Delphinula*, *Stylina*, Flem., *Volva* (*Ovula?*), *Volvaria*, *Dolium*, *Terebra*⁺, and *Assiminea*.

The Dentalium glabrum, Mont., and Dent. trachea, Mont., which come under the genus Cæcum of Fleming and Brochus of Brown, have been found at Miltown Malbay, on the coast of Clare, by Mr. W. H. Harvey, and at Bundoran, co. Donegal. Capt. Brown figures (pl. 1. Illustrations) three species of Brochus, which he calls new, from the coast of Ireland, viz. B. reticulatus and B. annulatus, from the county of Down; B. arcuatus from Bantry bay at this last locality B. striatus, Brown, occurred to myself. Naturalists seem not yet to have agreed about the position of this genus; some make it Annelidan. Mr. Clark of Bath (as I learn from Mr. Alder) proved it to belong to the Gasteropodous Mollusca. Philippi brings it—his genus Odontidium under Pteropoda.

The above species of *Cyclobranchia* perhaps include all those published that can be given with certainty as British.

Class ACEPHALA. Order BRACHIOPODA.

Turton mentions a single specimen of "Anomia terebratula" dredged alive in Dublin bay and placed in the museum of the Dublin Society. In August last, when visiting this collection in company with Mr. Alder, a Terebratula psittacea (sp.) labelled "Dublin bay," was observed, but whether it was the shell alluded to by Turton we could not ascertain. On looking over the Ordnance Museum we saw a specimen of *T. aurita*, which was dredged at the entrance of Belfast bay. Crania personata has been brought up from very deep water off Youghal by Mr. R. Ball, and has been obtained by Mr. John Humphreys on Pinna ingens, &c., dredged in Cork harbour and off Kinsale. The British

260

list contains but one species in addition to those named as Irish-the Ter. cranium, which is occasionally taken at Zetland.

About 220 species of Lamellibranchia are included in the British Fauna, of which 155 are Irish: to these, eight only—indicated in the usual manner in the preceding table—can be added, which have not a place in the catalogue of Great Britain, making the total number of Irish species 163. The marine species of that island unknown to us are the rarest there, not one of the many being common, and nearly all being local and confined to one district. It is not so with the freshwater species, Unio pictorum, U. tumidus, and Cyclas rivicola, which are more widely diffused, but at the same time become rare

* Pandora inæquivalvis (P. rostrata, Lam.). In Turton's catalogue of Irish Shells it is stated that specimens said to be from Bantry were shown him, but in his sub-

REPORT-1843.

towards the north of England, and are not found at all in Scotland. The generic forms wanting in Ireland are Lithodomus, Capsa, Panopæa, Galeoma, Unio, Crenatula, Neæra*, all of which, with the exception of Unio, are very rare :-- they have each but one representative British species.

In Loudon's Magazine of Natural History, vol. vii. p. 129, Mr. R. Templeton described and figured two species of the Moll. Tunicata, and eighteen more were recorded by myself in the Annals of Nat. Hist., vol. v. p. 93 :-- in the 13th volume of the latter work the additional species introduced here will be more particularly noticed. My knowledge of the Tunicata not being advanced beyond the identification of the species with those of the authors cited, the names are given in the consecutive order in which they appear in their works, without any attempt being made to bring the species ("simple" Ascidiæ) under their modern genera. Such of Muller's species as Savigny brought under certain of his genera have these added within brackets in the accompanying table.

* The introduced Dreissena is not included.

So little attention has been bestowed on the Mollusca Tunicata of Great Britain and Ireland, that it is perhaps unnecessary to draw the usual comparison. More Irish than British species can however be announced. Of the thirteen British simple Ascidians recorded, seven are Irish, in addition to which are eleven unrecorded as indigenous to the coasts of the larger island. Of the ten "compound" species published as British five are Irish, to which latter nine, unnoticed as indigenous to the seas of Great Britain, are to be added : all the species of the preceding catalogue marked (I.) are probably to be found on the British coast. So little of the history or geographical distribution of the Moll. Tunicata is known that the mere record of the species obtained in any locality possesses interest. The greater number of those here noticed are identical with the species found by Muller on the coast of Denmark; several, both of the "simple" and "compound," are the same as those of France described by Savigny and Milne Edwards, and a few of each division to those procured by Delle Chiaje on the coast of Naples.

Nearly all the species enumerated here were taken by dredging, as were a number of others (simple and compound) which are still undetermined. Professor Edward Forbes and Mr. John Goodsir, in the course of their dredging, have collected many species from various parts of the British coast, a very few of which are yet published.

To take a general view of the Mollusca of Ireland, as exhibited in the preceding catalogue, it would seem, regarding the subject positively, that a respectable knowledge of all the classes and orders has been acquired, and regarding it comparatively, that on the whole the species have been perhaps as well ascertained as those of Great Britain. The relative difference in the number of species (except perhaps in Nudibranchia) will probably hold good after the closest investigation of the subject in both islands : in the Bivalves only among the Testacea is the difference very striking. Considering the geographical position of the two islands, the smaller one being the farther removed from the great continental coast, the shores of Ireland being only about one-third the extent of those of the larger island, and what is of more consequence, limited to one-third of the degrees of latitude over which Great Britain with its neighbouring islands (whose fauna it includes) extend, the relative number of species known as Irish is as great as would à priori be anticipated.

CIRRHIPEDA.

The species of Irish Cirrhipeda known to Brown and Turton were included in their catalogues of "Testacea." Capt. Portlock, in bringing before the Royal Irish Academy (Jan. 23, 1837) a notice of Anatifa vitrea, read a list of the native Pedunculated Cirrhipeda, communicated to him by Mr.R.Ball*; and additional species have been contributed by myself to the Annals of Nat. Hist. vol. xiii.

The preceding catalogue exhibits nearly all the species of Cirrhipeda which have a place in the British Fauna; but as these have not been satisfactorily determined, the usual comparison is omitted. Several of the species can hardly be called natives of our seas, although found living on the bottoms of ships in our harbours, and attached to timber cast ashore; but by including them here I only follow British and French authors. Some species, if not native, have become naturalized to a limited extent, and take up their abode on the "wooden walls" of our docks, flood-gates, &c. The Coronula diadema, which has been obtained on the skin of whales killed on the British coast, and the Acasta Montagui, Leach, found imbedded in sponge, cannot be announced with certainty in the Irish catalogue.

CRUSTACEA.

Some species of Irish Crustacea have been recorded in the celebrated 'Zoological Researches' of Mr. John Vaughan Thompson, and his other writings[‡]; by Templeton's catalogue of all the species known to him, published in the ninth volume of Loudon's Magazine of Natural History; by contributions of Mr. Robert Templeton, to the second volume of the Entomological Transactions; and by communications of my own to the Annals of Natural History, vols. v. (pp. 221 & 255), vii. (p. 482), x. xi. & xiii.

The collections of Dr. Drummond, Mr. Hyndman and the Ordnance Survey, from the north-east coast; of Mr. R. Ball from Youghal and Dublin; of Dr. Bellingham (in *Syphonostomata*) from the last-named locality; and of

* The names of *Balanus communis*, *B. rugosus*, and *B. punctatus* have been applied to other species on the continent. See Lamarck, vol. v. 2nd edit.

† See correction of B. Scoticus and B. candidus in description of plate 32.

[‡] Papers in the Philosophical Transactions, 1835, and Entomological Magazine (vol.iii.), and Museum Catalogue of the Royal College of Surgeons, Dublin :—his whole collection of *Crustacea* now belongs to this College, and is exhibited in its museum;

Dr. Geo. J. Allman (Syphonostomata) from the coast of Cork, have, in ad-dition to my own, aided in this department. I have throughout followed the arrangement adopted in the excellent 'Histoire des Crustaces' of Milne Edwards.

Order PYCHNOGONIDA.

Nymphum gracile, Leach grossipes, Lin. (sp.)**

Of the thirty-six British species of Brachyura, all but six are known as Irish, and of these, one—Portunus marmoreus—is recorded as such, but the specimens so named which have come under my observation are P. pusillus (see Annals Nat. Hist. vol. x.); another—Portunus emarginatus—is believed to be only a variety of P. arcuatus, which is found around our coast. The other four species are Macropodia tenuirostris, Pisa Gibbsii, Polybius Henslowii, and Pinnotheres Montagui, all of which were known to Leach as in-

* Probably a species in its immature state.

† See Edw. Crust. vol. iii. p. 450.
 ‡ Ibid., p. 465.
 § Ibid., p. 495.
 || Merely indicated here; no author's name appended to the species.

¶ Foroculum Spratti is the name applied to a species in J. V. Thompson's Catal. Mus. Coll. Surg.

** A species of Ammothea is named A. aruginosa, and marked as Irish in J. V. Thompson's collection. Mus. Catal. Royal Coll. Surg. Ireland. See Edw. Crust. vol. iii. p. 534, for genus Ammothea.

habiting only the extreme southern coast of England. One species—Xantho rivulosus—has a place in the Irish and not in the British catalogue, but Professor Bell informs me that he has seen English specimens.

Of the Anomoura there are five British species, all of which are likewise Irish, and to the latter are to be added four or five species of *Pagurus* above indicated: what the *P. erinaceus* of Mr. J. V. Thompson is I do not know, but the four species named by myself are very distinct from each other, and unknown as British: whether they be all undescribed is yet to be determined. They were taken by Mr. Hyndman and myself when dredging in deep water in the loughs of Strangford and Belfast.

Of the twenty-six British Macroura * all but seven are recorded as Irish. Five of these—Axia stirhynchus, Gebia stellata, G. deltura, Hippolyte Prideauxiana, and H. Moorii-were known to Leach as from the south of Devonshire only: Hippolyte Sowerbæi was obtained at Newhaven, near Edinburgh; Penæus trisulcatus on the coast of Wales. Two species-Pasiphæa sivado and Palæmon Leachii-have a place in the Irish and not in the British list. The Decapodous Crustacea alone, I have critically studied throughout; consequently, so far only can a particular comparison of the species of the two islands be instituted : indeed of the British species belonging to the following orders, from Stomapoda to Pychnogonida inclusive, no proper catalogue is extant, and were those now known brought together and compared with the Irish species, the result would, as in the instance of the Annelida, simply denote how many belonging to each island had been determined, without giving any idea, as in the better studied portions of the Invertebrata, of the number positively, of each locality, or relatively, of the one island to the other. The undetermined Irish species in my own collection are perhaps thirty in number.

ANNELIDA.

About one-half of the Annelides in this catalogue were known to Templeton (Mag. Nat. Hist. ix.); the remainder, with the exception of a very few indicated by myself (Annals Nat. Hist. v. 247, vii. 482, and xiii.), have been investigated by my friend Dr. Johnston of Berwick-upon-Tweed, who kindly undertook to describe the species collected on the Irish shores (Annals Nat. Hist. v. p. 168 and 305, and vol. xiii.). He has likewise favoured me with a very elaborate manuscript catalogue of all the British Annelides on record with their numerous synonyma, and which it is but proper to mention, was drawn up with especial reference to a comparison of the British and Irish species in this Report. But, it is to be hoped that this catalogue will serve as the foundation of a work on the subject by Dr. Johnston.

Annelida?

Campontia eruciformis, Johnst., Loud. Mag. Nat. Hist. vol.viii. p.179.f.18. *

According to Dr. Johnston's catalogue, there is in the tribe Nemertina, one genus—Dalyellia, Flem.—known as British and not as Irish. Of twenty-nine British species seven are Irish; in addition to which are four—Borlasia? alba, Prostoma armatum, Planaria stagnalis and P. tremellaris—unnoticed as British.

274

In the tribe *Hirudina* are four British genera unknown as Irish—*Udonella*, Johnst., *Malacobdella*, Blain., *Tristoma*, Cuv., *Hirudo**. Of the eighteen British species nine are Irish, and in addition to the latter are *Piscicola percæ* and a new species of *Piscicola* \uparrow which is marine.

In Lumbricina, there is but one genus, Travisia, Johnst., unknown as Irish. Of the seventeen British species, eight are Irish, to which seven unrecorded as British are to be added[‡].

The tribe Serpulina § contains one British genus—Othonia, Johnst.—unknown as Irish, but as such only, the genus Ditrupa, Berk.||, is recorded. Of the fifty-three British species, twenty-two are described as Irish, in addition to which is the Ditrupa subulata.

Under Nereidina are nine British genera, Eunice, Schweig., Onuphis, Aud. and Edw., Myriana, Aud. and Edw., Psamathe, Johnst., Ioida, Johnst., Glycera, Lam., Leucodore, Johnst., Nerine, Johnst., Pholoe, Johnst., not included in the Irish catalogue. Of forty-five British species, fourteen are recorded as Irish, in addition to which are five undescribed as British, viz. Nereis Dumerilii, N. fucata, N. renalis, N. longissima, Spio calcarea (S. seticornis, Penn?). Of doubtful Annelides Dr. Johnston enumerates four species, belonging to as many genera; these are Campontia, Branchiarius, Mont., Diplotis, Mont., Derris, Adams: the first only is known as Irish. The whole of the recorded Annelides of Great Britain according to Dr. Johnston's catalogue are 167 species: the number known as Irish is 80¶. These numbers are useful only in denoting the species already known as indigenous to the respective islands, and give no idea of the number of species inhabiting our coasts and inland waters. In a forenoon's search several species might be added to either catalogue. About one-third of the British species were made known by Dr. Johnston, nearly all of which were previously undescribed.

FORAMINIFERA.

The native *Foraminifera* were included in the catalogues of Irish "Testacea" published by Capt. Brown and Dr. Turton, whose species have nearly all come under my own observation. The additional species, obtained and determined by Templeton and Mr. W. H. Harvey, were published in the Annals of Natural History, vol. v. p. 10, and those by Mr. Hyndman and myself will appear in vol. xiii. of the same work.

Spirolina	carinatula; Naut. carin., Mont	1	-	
Renoidea	rotundata, Brown, Illus. pl. 1. f. 14 and 15	*	*	15.00
"	glabra, Brown, Illus. pl. 1. f. 20, 21	*	*	-
	oblonga, Brown, ", f. 16, 17**	 	*	

* As now limited, Hir. medicinalis is the only British species.

† Dr. Johnston has since informed me that he likewise has an undescribed marine *Piscicola*.

[‡] These six are earthworms of the genus *Lumbricus* (see preceding catalogue) described by Templeton, with whom I agree in constituting them distinct species, but whether they be described as such by other authors I am not aware.

§ The genus Lobatula included in this tribe by Dr. Johnston is omitted here, but brought in under Foraminifera.

 $\parallel D.$ subulata only is brought under this genus in Dr. Johnston's catalogue. \parallel Many undetermined species are in my collection.

** In the second edition of Brown's Illustrations (of which a few parts are pub-

All the *Foraminifera* of the preceding list, except the two species described by Mr. R. Templeton, are known as British, and include about the one half of those brought together in Fleming's 'British Animals,' in 1828*. In Brown's 'Illustrations' seven species designated as new are figured :—three of these have now a place in the Irish catalogue. Mr. Macgillivray has in the present year added eight British species[†].

ENTOZOA.

A catalogue of the species of Irish *Entozoa* known to Templeton appeared in the ninth volume (p. 238-240) of Loudon's Magazine of Natural History. In the second and third volumes of the new series of the same work conducted by Charlesworth, Dr. J. L. Drummond published a series of articles on the subject, and in the fourth volume (p. 240 and p. 343) will be found a paper from Dr. Bellingham[‡], in which the species of *Filaria*, *Trichosoma*, *Trichocephalus*, *Oxyurus* and *Cucullanus*, which had come under his observation in Dublin, are recorded: also a notice of four species which occurred to him in the dissection of a sun-fish (*Orthagoriscus mola*). A remarkably copious manuscript catalogue of the *Entozoa* observed by Dr. Bellingham, has by his kindness been placed in my hands, and I shall give it just in the order (though much abbreviated)§ in which it has been com-

* The "Nautilidæ" of that work are all now considered Foraminifera, except Spirula australis (a cephalopodous mollusk), Orthocera imperforata, O. trachea, and O. glabra. The last three come under the genus Cæcum, Fleming, Brocus, Brown, Odontidium, Philippi.

† In Morris's 'Catalogue of British Fossils' just published, a great addition is made to the number heretofore known of the extinct species of Foraminifera.

[‡] Dr. B. has likewise published some papers in the Dublin Medical Journal and Dublin Medical Press on this subject.

§ The notes necessarily omitted here, are the most valuable portion of the catalogue, recording as they do the whole of the various animals in which upwards of 220 species of *Entozoa* were found by the author. These notes will be published in the thirteenth vol. of the Annals of Natural History.

REPORT-1843.

municated, adding within brackets in their proper places the species noticed by other naturalists, so as to present at one view the whole of the Entozoa known as Irish. Dr. Drummond has also contributed several species which were not treated of in his published papers. Dr. Bellingham remarks, " In furnishing this list of the indigenous Entozoa, I wish it to be understood that I have only inserted the species discovered and examined by myself, with the exception of two or three forwarded to me by my friends. The classification is that of Rudolphi, whose names for the species are adopted throughout unless otherwise expressed."

Spiroptera strumosa.

anthuris.

Trichosoma obtusum? inflexum? 23 longicolle. 22 plica. 22 Filaria attenuata. capsularia, Rud., Drum. M. N. H. 22 new series, iii. 230.] [Trichina spiralis, Owen, Allman, Microscopic Journal, vol. ii. p. 94.]

In this Order are nine species of Ascaris, two of Strongylus, six of Spiroptera, nine of Trichosoma, and three of Filaria undetermined by Dr. Bellingham.

The Irish species given in the preceding catalogue so far outnumber the British species known, that the usual comparison is uncalled for. Dr. Bellingham remarks, "The little attention which these animals have attracted in these countries will be apparent from the fact, that in the only works which contain lists of the British species of Entozoa, viz. Pennant's British Zoology, and Turton's British Fauna, but twenty-eight are described as indigenous, and four of these are noticed twice under different names, leaving but twentyfour distinct species; while in the limited opportunity which I have had, I have discovered and preserved upwards of 220 species, and several of these occurred in six, others in ten, and one species in as many as fifteen different animals." 'The number of Irish species determined by Dr. Bellingham is 143*; of species undetermined, but brought under their respective generat, eighty:---from the many works consulted, but in vain, for these latter, there is little doubt that the greater portion must be undescribed. Dr. Drummond too informs me that he has obtained many Entozoa which he believes to be new. The species recorded by Dr. Bellingham t were procured in Dublin; those by Templeton and Dr. Drummond in Belfast.

* Three species as indicated in a foot note are from British animals.

† Dr. Bellingham has some Entozoa which he cannot refer to any genus, and knows of several species having been obtained in Dublin, which are not included in his catalogue.

‡ Botriocephalus solidus is an exception, having been found by Dr. G. J. Allman in a Gasterosteus aculeatus taken in the co. of Cork-in specimens of this fish captured in the neighbourhood of Dublin Dr. Bellingham could never find this Entozoon.

In the arrangement and nomenclature of the preceding catalogue, the excellent work of Professor E. Forbes on the British Echinodermata is implicitly followed. The fullness with which the subject is treated in that work—to which all the information on the Irish species was contributed*, renders a few words only desirable here on the distribution of the species as yet unknown to our Fauna. Of the twenty-nine † species of British "Starfishes"-Crinoideæ, Ophiuridæ and Asteriadæ—all but five are recorded as Irish. These are Oph. punctata and Oph. Goodsiri, both of which were first described in Forbes's Brit. Echin.; the former has been taken only at Anstruther in Fifeshire; the latter there and at Shetland. Astrophyton scutatum and Goniaster equestris are both very rare, but have occurred at a few localities from north to south of Great Britain. Of Goniaster Abbensis (Forbes, Annals Nat. Hist. vol. xi. April 1843,) but a single individual has yet been met with, and as its name indicates, at St. Abb's Head. Of the eleven species of British Echinidæ, four are unknown to Ireland, but, one species -E. lividus - found on the western and southern coasts of the latter island, and unknown as British, makes our number eight. Of the desiderata, two-Cidaris papillata and Echinarachnius placenta-are extremely rare, and have been taken only in Shetland; Echinus neglectus there and in Orkney. Brissus lyrifer (first described in Forbes's Hist. Brit. Echin.) has been obtained only in the estuary of the Clyde. Of the twelve British species of Holothuriadæ, eight are known as Irish, and three-Cuc. Drummondii, Cuc. Hyndmani and Thyone Portlockii-discovered on the coast of the latter country and unknown as British, make the Irish species eleven in number. Of our desiderata, two species—Cucumaria hyalina and Cuc. fucicola—are known only to Shetland; Psolinus brevis to the same locality and the Kyles of Bute; Cucumaria frondosa to the same and the coast of Fife. Of the eight species of British Sipunculidæ four are known as Irish, in addition to which is the Sipun. Pallasii, that cannot be announced with certainty as British. Our desiderata are so rare that they have each been obtained in a single locality only on the British coast, namely, Syrinx nudus (with certainty) and Syr. Harveii at Teignmouth in Devonshire; Sipunculus Johnstoni at Berwick-upon-Tweed; Echiurus vulgaris at St. Andrews.

* Four species have since been added.

+ The original descriptions of two species-Oph. Ballii and Goniaster Templetoniwere drawn up from Irish specimens, and the first Cribella rosea noticed in the British seas was obtained off the south of Ireland.

ACALEPHA.

A catalogue of the Acalepha of Ireland known to Templeton was published in the ninth volume of Loudon's Magazine of Natural History; subsequently papers on the subject have been published by Mr. Patterson* and Mr. Hyndmant, and some additional species to our Fauna recorded by myself in the Zoological Proceedings for 1835, (p. 78)‡ and Annals of Natural History, vol. v. p. 248. Mr. R. Ball has, from observations made at Youghal and Dublin, contributed to our knowledge in this department. Distribution.

* Edin. Phil. Journ., Jan. 1836. Trans. Roy. Irish Acad. vol. xix. part 1. † Ann. Nat. Hist. vol. vii. p. 164. and vol. xiii.

‡ Physalia pelugica only is here noticed; two fine examples of this species have at different times been obtained at Youghal by Miss Ball.

§ A species of Velella is not uncommonly found thrown ashore on the north and west coasts, but being generally in an injured state, its species is uncertain. The V. emarginata is in all respects different from, and twice the size of the ordinary species. It was obtained on the coast of Cork some years ago by Dr. Geo. J. Allman. " "Probably as Cuvier suggests, some species in a mutilated state." Forbes. ¶ "Perhaps a young state of Aurelia." Forbes. ** " This and the preceding are badly observed species." Forbes. $\uparrow\uparrow$ "Of doubtful position, but apparently a good species." Forbes.

11 " Probably the fry of some species." Forbes. Lesson names it Thaumantias lucida, p. 335.

Professor Edw. Forbes, who has bestowed more attention on the Acalepha than any British author, and successfully studied the species in a living state, has kindly contributed for my use on the present occasion a catalogue of the native species, in which those observed by him when dredging in various parts of the Irish coast are noted: some of these have already been published in the Reports of the British Association for 1839 (p. 85, Transactions of Sections), and Annals of Nat. Hist. vol. vii. p. 81. The recorded species of British and of Irish Acalepha are about the same in number; the latter exclusively (as yet observed) are above indicated in the usual manner: those known as British and not as Irish, according to Professor Forbes's catalogue, are the following :—

"Cyanæa" coccinea, *Davis*, Ann. Nat. Hist.vol.vii.p. 234.pl.2. (Gen. Oceania.) "Geryonia" octona, *Flem.* Brit. Anim. (Gen. Oceania.) Aurelia granulata, *Esch.*

" purpurea, *Penn.* Cassiopea lunulata, *Penn.* "Eulimena" quadrangularis, *Flem.* Brit. Anim. (probably a Beroe.)

ZOOPHYTA.

The Zoophytes of Ireland are well known. In Ellis's British 'Corallines' some species from the coast of Ireland are described; in the ninth volume of Loudon's Magazine of Natural History a complete catalogue of the native Zoophytes known to Templeton appeared; in the 'Zoological Researches' of Mr. John Vaughan Thompson is a "memoir" (5th) partly upon the subject; in the Annals of Natural History, vol. v. p. 249, and vol. vii. p. 481, additional species to the Irish Fauna are given by myself; in vols. vi. vii. and ix. of this work Mr. Hassall has very fully entered into the subject; in the Proceedings of the Royal Irish Academy for 1843*, and in a communication brought before the present meeting †, Dr. Geo. J. Allman has given the results of his investigation of the freshwater species. The collections of Dr. J. L. Drummond and Mr. Hyndman from the north and north-east coast; of Mr. W. H. Harvey (communicated to me in 1834), Miss Ball, and Mr. R. Ball from the Dublin coast; of the two last-named from Youghal (co. Cork); of Mrs. Hancock from Ballysodare (co. Sligo), and others of less extent have added much-in addition to those of the naturalists who have written upon the subject—to our knowledge of the native species. To my kind friend Dr. Johnston I am indebted for a manuscript catalogue of the British Zoophytes as known to him at the present time : the nomenclature and synonyma of the following list are taken from it, as are, also, the data on which the concluding remarks are founded.

* The title of this paper is "On the Muscular System of Paludicella articulata and other Ascidian Zoophytes of fresh water."

Of the Zoophyta Hydroida there are fifty-two British species, five of which are not recorded as Irish: of these, three are each from a single locality-Corymorpha nutans, from Shetland; Sertularia Evansii, Yarmouth, and known only to Ellis; Laomedea obliqua, south of England? The others are Sertularia pinnata, of which nothing positive can be said, owing to the confusion in which the species is involved; Sertularia nigra, noticed on the east coast of Great Britain and in Cornwall. Cordylophora lacustris, a freshwater species discovered in the vicinity of Dublin by Dr. Geo. J. Allman, and for the reception of which he has constituted a new genus, has not been met with in Great Britain.

Ireland is very deficient in the Zoop. Asteroida, three only of the eight

* The preceding seven Lepraliæ have not been examined by Dr. Johnston.

† Flustra distans, Hass. not a veritable species.

British species having been found upon our coast: two of these eight-Gorgonia placomus, noted as from Cornwall (Ellis), and Isis hippuris, from the east of Scotland and Orkney-are considered by some authors as doubtful British species. The others are Pennatula phosphorea, for which the only localities particularized in Johnston's British Zoophytes are on the eastern coast of Scotland*; Gorgonia verrucosa from Cornwall, Devon, "Scotland;" Gorgonia lepadifera from Shetland and Aberdeenshire.

There are twenty British species of Zoophyta Helianthoida, including Capnea sanguinea, discovered in the Irish Sea near the Isle of Man by Professor Edw. Forbes. Nine of these have not been noticed on the Irish coast, and on the British, one only of the number has been found in more than a single locality, viz. Lucernaria campanulata, obtained at Torbay and Berwick. The others are the Capnea already mentioned; Turbinolia borealis and Actinia intestinalis from Zetland; Anthea Tuedia and Actinia saxatilis from Berwick; Act. biserialis from Guernsey; Iluanthus Scoticus from Loch Ryan.

The Actinia margaritifera and Act. coccinea found on the coast of Ireland, are unknown to the British catalogue.

The British species of Zoop. Ascidioida may be reckoned ninety-three in number †, after several species described as distinct have been made synonymous with others previously known; of these, twenty-eight have not yet been recorded as Irish :- several are yet unpublished as British. On the other hand, eight known as Irish have not a place in the catalogue of Great Britain; three are Lepraliæ described by Mr. Hassall; the Pedicellina echinata of Sars; Plumatella emarginata, Plum. fruticosa and Fredericella dilatata of Allman; Paludicella articulata of Gervais[‡]. Of the Irish desiderata seventeen species are each from a single British locality-Beania mirabilis and Flustra Murrayana from Scarborough; Tubulipora penicillata, T. deflexa, T. trahens and T. hyalina § (described by Mr. Conch), from Cornwall, which is the only locality for Retepora reticulata. Tubulipora truncata, Cellepora lævis, and Flustra setacea have been obtained at Zetland. Pallas's habitat for Notamia bursa-"mare Anglicum"-should probably be more strictly a limited locality. Lepralia trespinosa is from Berwickshire; Cellularia Hookeri from Torquay; Eschara fascialis, Isle of Wight; Lepralia reticulata, Aberdeen. The remaining species respecting which localities have been published, are Cellepora Skenei, east coast of Great Britain, &c., from Northumberland to Zetland, and lately dredged off the Mull of Galloway by Capt. Beechey, R.N.; Retepora cellulosa, Shetland, Fulah and Scarborough; Eschara foliacea, Sussex and the south coast of England.

AMORPHOZOA.

A catalogue of the Irish Sponges known to Templeton was published in the ninth volume of Loudon's Magazine of Natural History, and a few

* A specimen once brought to me from Belfast market was stated to have been found among haddock sent from Glasgow, and most probably captured on the west coast of Scotland.

† Included in this number are two of Delle Chiaje's species from Sana island, on the Scottish coast, noticed by myself in the Annals of Nat. Hist. (vol. x. p. 20), and the seven last-named species of Mr. Hassall in the preceding catalogue, all of which require to be further studied with the view to ascertain whether they be really new or only synonymous with species previously described-indeed, the Berenicea, Celleporæ and Lepraliæ require a thorough revision.

[†] A highly interesting paper on the anatomy of the species, by Dr. Geo. J. Allman, has been published in the Proceedings of the Royal Irish Academy for 1843.

287

additional species were noticed by myself in the fifth volume (p. 254) of the Annals of Natural History. More recently, the native species obtained by Mr. Hassall, myself and others, and those procured by Wm. McCalla, collector to the Royal Dublin Society, were placed in Dr. Johnston's hands for description in his work on the British Sponges which appeared in 1842. They are fully treated of there, with the exception of one species, the *Grantia lacunosa* (which I obtained in Strangford lough in July 1838) being accidentally omitted. The names in the following list are those adopted in the work just mentioned.

288

have been met with in Ireland, and 5 species—Halichondria simulans, H. ægagropila, H. saburrata, H. carnosa, Grantia fistulosa; all described as new being indigenous to the latter island only, make our number thirty-two. The most common Halichondriæ thrown ashore on the north-east coast of Ireland are H. fucorum and H. panicea: on the Dublin coast the latter is in the highest perfection. H. suberea is not uncommonly dredged from deep water. Spongilla fluviatilis is found in several localities in the north, and both in swiftly-flowing and still waters.

Grantia compressa and G. ciliata are common on Alga around the coast, as G. botryoides is in the north.

Of the twenty-four British Sponges unknown as Irish, the following species are recorded but from one district or one locality-Geodia Zetlandica and Tethea cranium, Shetland Isles-Halichondria hispida, H. ramosa, H. plumosa, H. fruticosa, H. aurea, H. conus, H. rigida, H. perlevis; Spongia lævigata and Pachymatisma Johnstonia from the south of England: of these ten species, seven rest on the authority of Montagu alone. Halich. aculeata and H. virgultosa are from Scarborough (Mr. Bean); Halich. albescens and Halisarca Dujardinii from Berwick and its vicinity (Dr. Johnston); Halich. sevosa from the Isle of Man (Mr. E. Forbes); Spongilla lacustris from the adjoining counties of Angus (or Forfar) and Fife; the remainder are Halich. palmata found in the Orkney and Shetland Islands, the east and south of England; Halich. Columbæ, Icolmkill and Brighton; Halich. infundibulum, northern islands of Scotland and Cumbrae; Halich. coalita, east and south Great Britain; Halich. ficus, Scarborough and Isle of Man; Grantia pulverulenta, Devon and Zetland. Of the eight British species (or forms considered as such) of Lithophyta, four are known as Irish, and in the catalogue of the latter, two new species-Nullipora fasciculata and N. agariciformis—are included, thus making the number altogether six. Corallina officinalis, Jania rubens, and Nullipora polymorpha, are abundant round the coast. Of the four British species unknown as Irish, three—Corallina elongata, C. squamata and Jania corniculata -have been found only in the south of England; Nullipora calcarea there, and also on the west coast of Scotland : this last is considered by Dr. Johnston to be merely a state of N. polymorpha.

Conclusion.

The progress made in the portions of the Invertebrata of Ireland embraced in this Report has been indicated under the respective Classes. It is considerable in all, and exhibits, from the circumstance of our Fauna being about equally investigated with that of Great Britain, a fair comparison with the larger island*. Much still remains to be done in every department with reference to mere species, and to their distribution. The manner in which the various marine species are found associated together; the relative depths considered in connection with their mineralogical character; the many influences affecting the distribution of species, are subjects of inquiry, for the study of which the coast of Ireland offers a rich harvest[†]. Accurate observations on the habits and general economy of the species are always valuable. The

* More attention has been bestowed on the Mollusca Nudibranchia, Foraminifera and Annelida of Great Britain than on those of Ireland, where on the other hand the Mollusca Cephalopoda, Moll. Tunicata and Entozoa have (as to species) claimed more attention.

† The natural history of Ireland exclusively being alluded to, the all-important questions of structure and physiology are not mentioned, as they can be studied in

289

following is a brief summary of the departments in which the greatest additions to our knowledge as to species, &c. may be anticipated :-- MOLLUSCA, Orders Nudibranchiata and Tunicata generally; Cephalopoda—as evinced by Mr. R. Ball's discoveries in one locality; Pectinibranchiata—minute species of the families Turbinidæ and Buccinidæ; Lamellibranchiata—in the species not to be met with on the beach, but only to be obtained by dredging. CRUSTACEA generally, excepting the order Decapoda. CIRRHIPEDA, with respect to the various forms assumed by each species. ANNELIDA generally, land, freshwater and marine: the testaceous species of the tribe Serpulina, though as to their mere number the best known, much require rigid analysis. FORAMINIFERA generally. ECHINODERMATA, the families Holothuriada and Sipunculidæ. ACALEPHA generally. ZOOPHYTA; in Hydroida, the soft species or those which do not form horny cases, as the genera Clava, Hydra, &c.; the Helianthoida generally; in Ascidioida, the genera Tubulipora and Lepralia, in reference to the extent of form assumed by the respective species. AMORPHOZOA or Sponges generally. ENTOZOA generally—tracing the forms assumed by the respective species from birth to their adult state, &c. The chief collections of objects illustrative of the Zoology of Ireland are the following. In Dublin there are of public collections, the Ordnance Museum, Phœnix Park, good in various departments of Vertebrata and Invertebrata; the Royal College of Surgeons Museum, in which Mr. J. V. Thompson's collection of Crustacea is preserved; Trinity College, containing the late Mr. Tardy's fine collection of Insects, added to by Dr. Coulter; Natural History Society, Zoophytes, &c.; Royal Dublin Society, Vertebrata and Invertebrata: of private collections there are in the metropolis Mr. R. Ball's, very rich in the various branches of Vertebrata and Invertebrata; Miss M. Ball's, Insects chiefly, and Shells; Mr. Warren's, very fine in Shells and Birds; Dr. Farran's, also very fine in Shells, and good in Birds; Dr. Bellingham's, in Entozoa; Mr. Egan's, in Insects; Dr. George J. Allman's, in freshwater Zoophytes and Mollusca Nudibranchiata; Mr. O'Kelly's, in Shells *. In Belfast, the Museum of the Natural History Society contains a general collection of Vertebrata and Invertebrata, including the late Mr. Templeton's; Mr. Hyndman's collection is rich in Mollusca, Insects, &c.; Mr. Haliday's very rich in some orders of Insects; Dr. Drummond's in Entozoa and various Invertebrata; Mr. Patterson's in Insects; my own in various departments, Vertebrata and Invertebrata. In Cork, Dr. Harvey has a good collection of Vertebrata, as Mr. Clear has of Insects; Mr. Humphreys, of Shells; Mr. Samuel Wright, of Shells, &c.: Mr. Samuel Green of Youghal has a good collection of the eggs of native birds. In Limerick, Mr. Wm. Henry Harvey has a good collection of land, freshwater and marine Shells. In the county of Tipperary Mr. Robert Davis, Jun. of Clonmel, has a collection of Birds, and of the Eggs of Birds, the best in Ireland : the Rev. Thomas Knox of Toomavara has a good collection of Birds, as Mr. Edward Waller of Finnoe has of land and freshwater Shells: the late Mr. Hely had an extensive collection of the Insects of his district. Dr. Burkitt of Waterford has a large collection of Birds. Mr. John Vandeleur Stewart of Rockhill, Letterkenny, county of Donegal, has an extensive collection of Mammalia and Birds :- the Rev. Benj. J. Clarke, now of Tuam, of land and freshwater Mollusca :-- Mrs. W. J. Hancock of Lurgan, of Shells, &c., from two localities on the western coast. The collection of Irish Shells formed by Capt. Brown now belongs to Lady Jardine, and that of Dr. Turton is in the possession of Mr. Jeffreys of Swansea.

* This collection having been formed previous to the publication of the catalogues

Finally, it should be stated that the various Classes of the Vertebrate and Invertebrate animals of Ireland contained in this and the former Report are not treated of for the first time. They were all studied by JOHN TEMPLÉ-TON, and catalogues of the species they embrace, with the exception of Mollusca (omitted only because others had written on it), were published from his manuscript by his son (who is likewise most favourably known to zoologists) in the ninth volume of Loudon's Magazine of Natural History, and in the first volume of the same work conducted by Charlesworth: the former volume contains the Invertebrata; the latter, the Vertebrata.

The only portions of the Animal Kingdom as displayed in Ireland and not included in this Report (two parts), are Insecta (including *Myriapoda*, *Arachnoida*, &c.) and Infusoria. That the Insecta have not been altogether neglected, the following summary, kindly contributed by Mr. A. H. Haliday, will show. This distinguished entomologist remarks,—

290

"My catalogue, which has lain untouched for several seasons, contained of named and described species—

"Coleoptera, about 950. A good many of these from Mr. Tardy's MSS., and as his health for some years previous to his death had not allowed him to follow the progress of science, the additions from this source may require some revision.

"Some particulars as to Irish Coleoptera are given in Entomologist, Annals of Nat. Hist. vol. ii. Entom. Magazine, vol. iv.

" Strepsiptera, 2 species.

" Orthoptera, about 50. See Ent. Mag. vol. iii. iv.

"Hemiptera, under 150. The order very little examined yet.

"Diptera, about 1050. Annals Nat. Hist. ii. & iii. Zool. Journal, v. Ent. Mag. i. iii. iv.

"Hymenoptera, about 1100. Annals Nat. Hist. ii. Ent. Mag. 1-5. F. Walker, Monographia Chalciditum; A. H. Haliday, Hymenoptera Britannica. "Lepidoptera, about 450, chiefly from Tardy's MSS. and collection, and requiring revision, as they had fallen into confusion. I had the liberty of avail-

ing myself of these from the late possessor, Dr. Coulter.

"Thysanura, about 22, collected by me. See Templeton in Trans. Ent. Society, vol. i. p. 89.

"Neuroptera, about 70.

"Total number of Irish Insects known, about 3850.

"Some additions in each I owe to W. Clear, Esq., and the collections, &c. of the late G. Hely and — Hafield, but I suppose nine-tenths of the whole (except *Lepidoptera*) were taken near Belfast; so that independent of the numbers unexamined and unnamed the selection affords no clue to the numbers of *Irish* Fauna. I have had opportunity however to judge that the south of Ireland does not afford the same increase of *forms* which we find in the like change of latitude in Great Britain.

"Stephens and Curtis both give, scattered throughout their principal works, information about the insects found in Ireland. There are also a *few* detached notices elsewhere which I cannot just now refer to."

To the above from Mr. Haliday it may be added, that some species found in the north of Ireland are incidentally noticed in Patterson's volume on the 'Insects mentioned in Shakspeare's Plays;' and that in Mr. Denny's work

PROVISIONAL REPORTS AND NOTICES. 291

list of the *Myriapoda*^{*} and *Arachnoida*⁺. The *Infusoria* have been little attended to: some native genera and species placed by some authors in the Animal Kingdom are described in Harvey's 'Manual of the British Algæ:' others of a similar nature have been brought before the Microscopical Society of Dublin by Capt. Portlock \ddagger and Mr. David Moore \S . Dr. Geo. J. All-man \parallel has likewise exhibited to that Society a few species of *Infusoria*, which it is unnecessary to name here.

In concluding this Report, it may be permitted me to state that no one can be more sensible than myself of its numerous imperfections. With the hope of diminishing their number by a more extended time, I was desirous of its postponement for another year, but it was urged that a Report on the Fauna of Ireland should be brought forward at an Irish meeting of the Association, and to this consideration I at length waived my desire for a longer period of preparation.

PROVISIONAL REPORTS AND NOTICES OF PROGRESS IN SPECIAL RESEARCHES ENTRUSTED TO COMMITTEES AND INDIVIDUALS.

Report on the Results of the Discussion of the Meteorological Observations made at Plymouth and Devonport at the request of the Association. By WM. SNOW HARRIS, F.R.S.

THE great mass of the results which these observations necessarily involved had precluded the possibility of completing a full report, such as would be requisite for the pages of the next volume of the Association : the necessary documents are, however, sufficiently complete to insure this report for the next meeting.

The first series of observations were those deduced from Mr. Whewell's anemometer, by which a result has been arrived at not dissimilar from that laid before the Meeting at Manchester, viz. the existence of a sort of tradewind or current of air from south to north, in the place where the observations were made: this was exemplified by large typographical delineations of the aërial currents by lines proportional to the velocity and direction for given times laid down for the years 1841 and 1842. Mr. Harris made some observations on the nature and capabilities of this instrument, and the results which might be expected from it in deducing the great annual movements of the atmosphere. The result of the discussions of the observations with Osler's anemometer were next brought under consideration, which being regularly tabulated and discussed, indicated a mean hourly intensity of the wind in an order similar

* Loudon's Mag. Nat. Hist. ix.

 \uparrow Id. and Zool. Journ. vol. v. p. 400. A singular parasite obtained on a Grey Seal (*Halichærus gryphus*) killed on the Dublin coast by Mr. R. Ball, has been investigated by Dr. Geo. J. Allman, who brings it under *Arachnoida* and constitutes a new genus—*Halarachne*—for its reception. He proposes to call the species *Halar. halichæri*: it will be described in the Annals of Natural History.
